The Sparks Foundation: Task 2- Unsupervised Learning (K Means Clustering) - Iris Dataset

K- Means Clustering Assignment - 2

Author: Maram Ramya

1)Importing the libraries

```
# Importing the libraries
 import numpy as np
 import matplotlib.pyplot as plt
 import pandas as pd
 import seaborn as sns
 from sklearn.cluster import KMeans
 %matplotlib inline
```

2) Importing the dataset

```
df = pd.read_csv(r"C:\Users\dell\Downloads\Iris.csv")
In [3]:
           df.head()
             Id \quad SepalLengthCm \quad SepalWidthCm \quad PetalLengthCm \quad PetalWidthCm \\
Out[3]:
                                                                                  Species
          0 1
                             5.1
                                             3.5
                                                             1.4
                                                                            0.2 Iris-setosa
                             4.9
                                             3.0
                                                             1.4
                                                                            0.2 Iris-setosa
                                                                            0.2 Iris-setosa
          2 3
                             4.7

In [10]: # now we will drop the label column because it is an unsupervised learning problem

Out[10]: SepalLengthCm SepalWidthCm PetalLengthCm PetalWidthCm 0 3.5 0.2 4.9 3.0 0.2 2 4.7 3.2 1.3 0.2 0.2 4.6 3.1 3.6 0.2

3) Finding the optmium number of clusters

Before clustering the data using kmeans, we need to specify the number of clusters. In order to find the optimum number of clusters, there are various methods available like Silhouette Coefficient and the Elbow method. Here, the elbow method is used.

Brief about the Elbow method

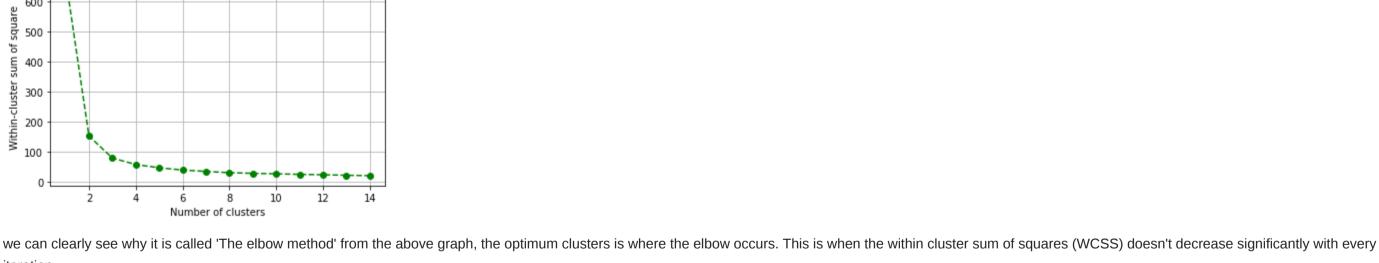

In [11]: # Calculating the within-cluster sum of square

In this method, the number of clusters are varies within a certain range. For each number, within-cluster sum of square (wss) value is calculated and stored in a list. These value are then plotted against the range of number of clusters used before. The location of bend in the 2d plot indicates the appropriate number of clusters.

```
within_cluster_sum_of_square = []
          clusters_range = range(1,15)
          for k in clusters_range:
              km = KMeans(n_clusters=k)
             km = km.fit(iris_df)
             within_cluster_sum_of_square.append(km.inertia_)
In [12]: # Plotting the "within-cluster sum of square" against clusters range
```

plt.plot(clusters_range, within_cluster_sum_of_square, 'go--', color='green') plt.title('The elbow method')

plt.xlabel('Number of clusters') plt.ylabel('Within-cluster sum of square') plt.grid() plt.show() The elbow method 700 600

iteration. From this we choose the number of clusters as '3'

4) Training the KMeans model on the dataset

```
In [13]: from sklearn.cluster import KMeans
          model = KMeans(n_clusters = 3, init = 'k-means++', max_iter = 300, n_init = 10, random_state = 0)
          predictions = model.fit_predict(iris_df)
```

5) Visualising the clusters¶ In [14]: x = iris_df.iloc[:, [0, 1, 2, 3]].values

```
plt.scatter(x[predictions == 0, 0], x[predictions == 0, 1], s = 25, c = 'red', label = 'Iris-setosa')
plt.scatter(x[predictions == 1, 0], x[predictions == 1, 1], s = 25, c = 'blue', label = 'Iris-versicolour')
plt.scatter(x[predictions == 2, 0], x[predictions == 2, 1], s = 25, c = 'green', label = 'Iris-virginica')
# Plotting the cluster centers
plt.scatter(model.cluster_centers_[:, 0], model.cluster_centers_[:,1], s = 100, c = 'yellow', label = 'Centroids')
plt.legend()
plt.grid()
plt.show()
4.5
4.0
```

```
3.0
                                                       Iris-setosa
2.5
                                                      Iris-virginica
                                                      Centroids
```
